EEL 4713 – Computer Architecture
Midterm Exam
Thursday, March 22nd, 2007

NAME:

Please read each question carefully, to avoid any confusion. This exam should have a total of 14 pages, printed double-sided. Pages 9-14 have reference information and scratch space. Before you begin, make sure your copy contains all pages. The exam is closed book, closed notes. Each question has its number of points identified in brackets.

GOOD LUCK!

QUESTION	***POINTS SCORED***
1 [40]	
2 [25]	
3 [15]	
4 [20]	
TOTAL	

1) [40] This question considers the addition of new instructions to the MIPS ISA:

a) [20] Consider the additional of a “conditional load word/clear” instruction:

clwr rd,rs,rt (rs, rd, rt are the R-type opcode fields)

Which behaves as follows:

```
if $rs is zero
        $rd = MEM[$rt]
else
        $rd = 0
```

Determine which new components and connections need to be added to the **single-cycle datapath** to support this new instruction. List each component, its connections and why they are needed in the space below (alternatively, you may draw each component and its connections in the single-cycle schematic in page 9).

b) [20] Consider the additional of a “conditional register copy” instruction:

crcp rd,rs,rt (rs, rd, rt are the R-type opcode fields)

Which behaves as follows:

```
if $rs is zero
        $rd = $rt
else
        do nothing
```

As in part a), determine which new components and connections need to be added to the **multi-cycle datapath** to support this new instruction. In addition, determine the new states needed in the control logic to implement this instruction; be sure to list the control bits that need to be asserted in each state and the state transitions. See pages 10 and 11 for the multi-cycle datapath and control state machine.

2) [25] Consider the decimal numbers A=31.75 and B=768.375

a) [5] Determine the single-precision floating-point encoding of these two numbers.

b) Suppose A,B are multiplied using floating-point hardware.

i) [10] What are the two operands provided as inputs to the exponent “small ALU”? What is the exponent of the single-precision number resulting from this multiplication?

ii) [10] Suppose the mantissas are handled by an implementation following Booth's algorithm. How many addition and subtraction operations are required to multiply these two numbers? Explain. (Hint: you do not need to actually perform the multiplication).

3) [15] You consider improving a processor's performance by implementing changes to its organization that will reduce the CPI of a certain instruction type by exactly one cycle. Design constraints are such that you must choose a single instruction type to optimize.

a) [10] Suppose the average mix of instructions is 25% loads, 25% stores, 20% branches, 30% ALU, and that the CPIs before optimization are 5 (load), 4 (store), 3 (branch) and 4 (ALU). Which optimization would lead to the best speedup?

b) [5] Suppose the optimization chosen in part a) would require extending the clock cycle by 1%. What would the overall speedup be for the optimized system?

4) [20] Answer the following multiple-choice questions; be sure you read *all* options before making your choice.

a) [5] Circle **one** correct answer. What metric is used to calculate SPEC CPU results?

1) Number of instructions executed.
2) Average clocks cycles per instruction.
3) Clock rates
4) Normalized execution times

b) [5] Circle **one** correct answer. Consider a program P compiled with two different compiler flag settings (F1 and F2) for a multi-cycle MIPS computer C. The instruction count of P with flag F1 is 1,000, while the instruction count with flag F2 is 1,010.

1) The performance of P compiled with flag F1 is better than the performance with flag F2 in computer C
2) The performance of P compiled with flag F2 is better than the performance with flag F1 in computer C
3) The relative performance of program P compiled with flags F1 and F2 cannot be determined without additional information

c) [5] The exponent in single-precision floating-point representation is 'biased' by a constant because:

1) It facilitates the addition of floating-point numbers
2) It facilitates the multiplication of floating-point numbers
3) It facilitates the division of floating-point numbers
4) It facilitates the comparison of floating-point numbers
5) None of the above

d) [5] What is a possible justification for the MIPS "jump and link" instruction to implicitly store the PC+4 value to a fixed register (R31) as opposed to allowing an arbitrary register to be used?

1) To facilitate the compilation of recursive subroutines
2) To support as large as possible an immediate value for the target address
3) To simplify the design of the register file hardware
4) To achieve a reduction in the effective CPI of the jump-and-link instruction in multiple-cycle datapath
